POPULATION GENETICS · THEORETICAL MODEL

The Jesus DNA Hypothesis

One man. One son. 2,000 years. What survives?

1 male · 30 AD · Judea
80 generations modeled
Y-line + mtDNA + autosomal

The premise: If a single man from 1st-century Judea had a son, only one piece of his DNA would survive intact today — the **Y-chromosome**, a biological "receipt" passed father → son without shuffling. It makes up **0.9% of a man's genome**, but after 80 generations, that receipt is still a **99.99998% match** to the original. This report traces that signal — and asks who might carry it.

01 — THE Y-CHROMOSOME: RECEIPT, NOT BLUEPRINT

99.99998% match to the original after 2,000 years

Size	~57 million base pairs
Share of male genome	0.9%
Mutations over 80 gen.	~13–14 (out of 57M)
NRY (non-recombining)	~95% of the Y
Likely haplogroup	J1 or J2

WHAT'S INSIDE THE Y-CHROMOSOME:

SRY: master switch for male development · **AZF:** sperm production (line dies without it) · **NRY:** the "serial number" — doesn't build anything visible, but traces the unbroken chain of fathers across millennia. This is the *entire* forensic signal.

02 — DOES THE LINE EVEN SURVIVE?

95–97% chance the line is extinct today. Most male lines die within 20 generations — one generation of only daughters and it's over forever. But if it survived that gauntlet, it branched enough to become permanent. The question isn't *if* carriers exist — it's *how many*.

03 — IF THE LINE SURVIVED: THE "CLUB" BY THE NUMBERS

0.9%	~200K	1 in 20K	0.005%	80
of genome per carrier	est. male carriers alive	men on Earth	of all men worldwide	unbroken generations

CONSERVATIVE	MODERATE ⋆	UPPER BOUND
50K–100K men	**200K–500K men**	**~1 million men**
Stayed in Galilee villages, minimal branching	Regional Levant spread + modern diaspora	Strong branching + Ottoman/colonial migration

04 — WHAT ABOUT WOMEN?

Mary's Receipt: mtDNA

Women have their own "receipt" — **mitochondrial DNA**, passed mother → daughter unchanged. If Mary had daughters, their maternal-line descendants carry her mtDNA today: a **99.999%+ match** across 80 generations. It's only **~16,500 base pairs** (0.0005% of genome) but it's an equally unbroken chain — just tracing the *maternal* line instead.

The Actual Blueprint: Autosomal

The DNA that coded for Jesus's **face, skin, hair, immune system** — everything physical — is on the **22 autosomal chromosome pairs**. These are inherited **equally by sons and daughters**. In endogamous Levantine communities, both sexes carry the same ~93% Canaanite ancestry. **Women carry the same physical heritage as their brothers.** The Y is just a tracking number — the blueprint is shared.

The Y-chromosome is the "receipt." The autosomal DNA is the "product." Women got the product — they just didn't get the receipt.

05 — WHERE WOULD CARRIERS BE?

Within any single community, only **5–15% of men** would carry this specific Y-line — the rest carry parallel lineages from other 1st-century men. In small isolated villages, the share could be 25–30%. In cities like Beirut, 1–2%.

06 — CONTEXT: KNOWN Y-LINE EXPANSIONS VS. THIS HYPOTHESIS

LINEAGE	CARRIERS	DRIVER
Genghis Khan (~1200 AD)	~16M	Empire + harems
Giocangga / Manchu (~1550 AD)	~1.5M	Qing dynasty rule
Niall of Nine Hostages (~400 AD)	~3M	Irish royal dynasty
Hypothetical Judean (30 AD)	~200K	No power, regional
Average man, any era	0	Most lines go extinct

Why ~200K and not millions?

Genghis Khan's Y-line exploded because **empire gave his sons extreme reproductive advantage** — wealth, harems, political power across Asia for centuries. A 1st-century Judean craftsman had none of that. His line would have grown through **quiet village persistence** — fathers having sons in the same mountain valleys, generation after generation, for 2,000 years. No conquest. No empire. Just endurance.

That's what makes it remarkable: if those ~200K men exist, their Y-chromosome has survived the Roman Empire, the Crusades, the Ottoman centuries, and two World Wars — not through power, but through the sheer stubbornness of biology.

Theoretical framework. Y-chromosome size (0.9%, ~57 Mb) and mutation rate are verified measurements. Survival probabilities derive from Y-lineage extinction models. Carrier estimates extrapolate from Genghis Khan (Zerjal 2003) and Niall (Moore 2006) parallels, adjusted for no reproductive advantage. The 93% Canaanite figure (Haber 2017) describes population-level shared ancestry — not descent from one individual. No claim is made about any specific historical figure. This is a mathematical exercise: one man, one son, what happens over 80 generations.
